

NAÏVE BAYES CLASSIFIERS

RECAP

Probabilistic agent has a numerical degree of belief between 0 (false) and 1 (true)

Unconditional Probability

- P(a), the probability of "a" being true, or P(a=True)
- Does not depend on anything else to be true (unconditional)
- Represents the probability prior to further information that may adjust it (prior)

Conditional Probability

- P(a|b), the probability of "a" being true, given that "b" is true
- Relies on "b" = true (conditional)
- Represents the prior probability adjusted based upon new information "b" (posterior)
- Can be generalized to more than 2 random variables: e.g. P(a|b, c, d)

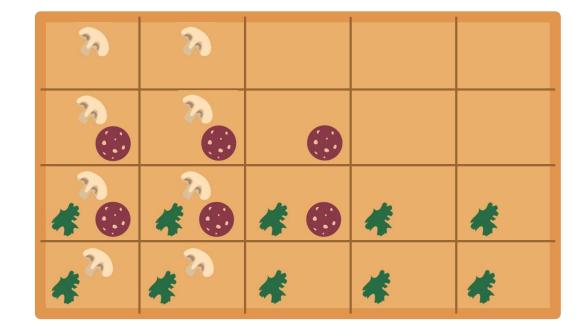

Joint Probability

- P(a, b) = P(a ^b), the probability of "a" and "b" both being true
- Can be generalized to more than 2 random variables: e.g. P(a, b, c, d)

ANSWER ANY QUERY FROM JOINT DISTRIBUTION

What is the probability of getting a slice with:

- 1) No mushrooms
- 2) Spinach and no mushrooms
- 3) Spinach, when asking for slice with no mushrooms
- Mushrooms
- Spinach
- No spinach
- No spinach and mushrooms
- No spinach when asking for no mushrooms
- No spinach when asking for mushrooms
- Spinach when asking for mushrooms
- No mushrooms and no spinach

Icons: CC, https://openclipart.org/detail/296791/pizza-slice

ANSWER ANY QUERY FROM JOINT DISTRIBUTION You can answer all of these questions:

	P(M)		P(M,S)				
m_1	12/20	m_1	s_1				
m_2		m_1	S_2	6/20			
	P(S)	m_2	S_1				
s_1		m_2	S_2				
s_2							

P	$(M s_1)$	P	$(M S_2)$
m_1		m_1	
m_2		m_2	
P	$P(S m_1)$) P	$2(S m_2)$
s_1		s_1	
s_2	6/12	s_2	

ANSWER ANY QUERY FROM JOINT DISTRIBUTION

P(Weather)?

P(Weather | winter)?

P(Weather | winter, hot)?

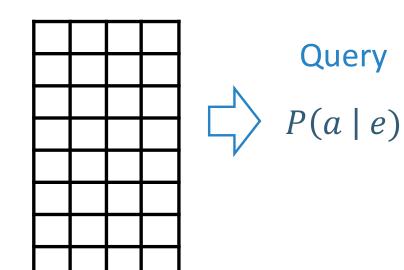

Season	Temp	Weather	P(S, T, W)
summer	hot	sun	0.30
summer	hot	rain	0.05
summer	cold	sun	0.10
summer	cold	rain	0.05
winter	hot	sun	0.10
winter	hot	rain	0.05
winter	cold	sun	0.15
winter	cold	rain	0.20

ANSWER ANY QUERY FROM JOINT DISTRIBUTION

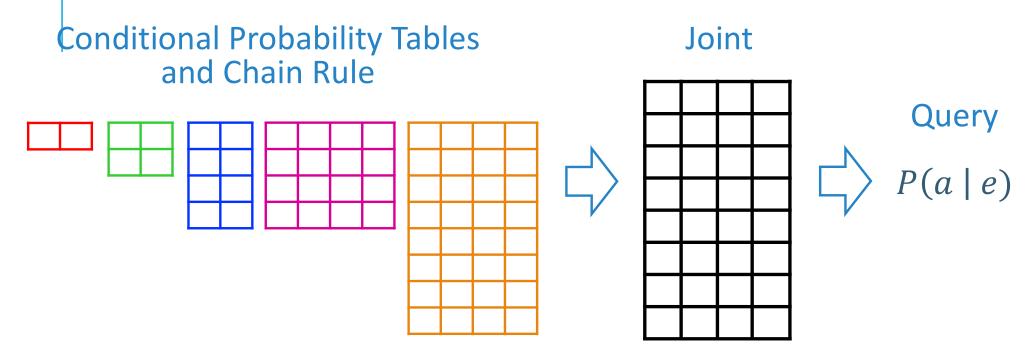

Joint distributions are the best!

Problems with joints

- Huge
 - n variables with d values
 - d^n entries
- We aren't given the joint table
 - Usually some set of conditional probability tables

BUILD JOINT DISTRIBUTION USING CHAIN RULE

P(A) P(B|A) P(C|A,B) P(D|A,B,C) P(E|A,B,C,D)

BUILD JOINT DISTRIBUTION USING CHAIN RULE

Two tools to construct joint distribution

1. Product rule

$$P(A,B) = P(A \mid B)P(B)$$

$$P(A,B) = P(B \mid A)P(A)$$

2. Chain rule

$$P(X_1, X_2, ..., X_n) = \prod_{i} P(X_i \mid X_1, ..., X_{i-1})$$

$$P(A, B, C) = P(A)P(B \mid A)P(C \mid A, B)$$
 for ordering A, B, C

$$P(A, B, C) = P(A)P(C \mid A)P(B \mid A, C)$$
 for ordering A, C, B

$$P(A, B, C) = P(C)P(B \mid C)P(A \mid C, B)$$
 for ordering C, B, A

...

USING THE PRODUCT RULE

- Applies to any number of variables:
 - P(a, b, c) = P(a, b|c) P(c) = P(a|b, c) P(b, c)
 - P(a, b, c | d, e) = P(a | b, c, d, e) P(b, c | d, e)
- Factoring: (AKA Chain Rule for probabilities)
 - By the product rule, we can always write:

$$P(a, b, c, ... z) = P(a | b, c, ... z) P(b, c, ... z)$$

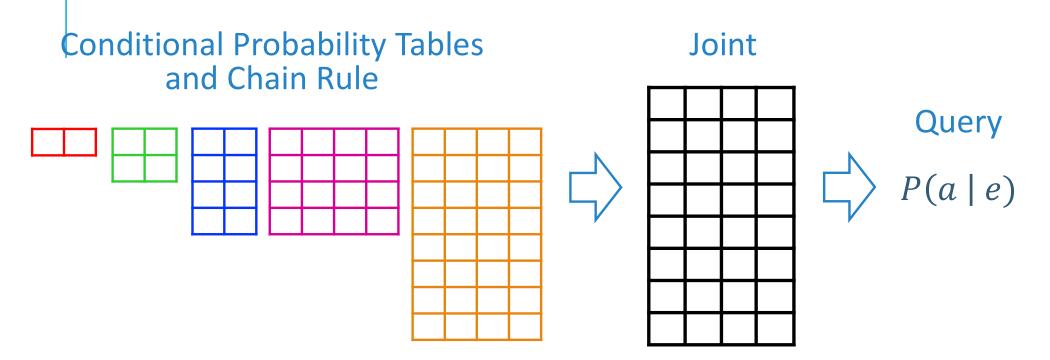

We often use comma to abbreviate AND.

Repeatedly applying this idea, we can write:

$$P(a, b, c, ... z) = P(a | b, c, z) P(b | c, ... z) P(c | ... z) ... P(z)$$

This holds for any ordering of the variables

ANSWER ANY QUERY FROM CONDITION PROBABILITY TABLES

P(A) P(B|A) P(C|A,B) P(D|A,B,C) P(E|A,B,C,D)

ANSWER ANY QUERY FROM CONDITION PROBABILITY TABLES

Process to go from (specific) conditional probability tables to query

Construct the joint distribution

Product Rule or Chain Rule

Answer query from joint

- Definition of conditional probability
- Law of total probability (marginalization, summing out)

ANSWER ANY QUERY FROM CONDITION PROBABILITY TABLES

Bayes' rule as an example

Given: P(E|Q), P(Q) Query: P(Q|e)

Construct the joint distribution

- Product Rule or Chain Rule
- P(E,Q) = P(E|Q)P(Q)

Answer query from joint

- Definition of conditional probability
- $P(Q \mid e) = \frac{P(e,Q)}{P(e)}$
- Law of total probability (marginalization, summing out)

$$P(Q \mid e) = \frac{P(e,Q)}{\sum_{q} P(e,q)}$$

BAYESIAN NETWORK

TYPES OF CLASSIFIERS

- We can divide the large variety of classification approaches into three major types
 - 1. Instance based classifiers
 - √Use observation directly (no models)
 - ₹e.g. K nearest neighbors
 - 2. Generative:
 - ₹build a generative statistical model
 - ₹e.g., Bayesian networks
 - 3. Discriminative

 - ₹e.g., decision tree

BAYES DECISION RULE

 If we know the conditional probability P(X | y) we can determine the appropriate class by using Bayes rule:

$$P(y = i \mid X) = \frac{P(X \mid y = i)P(y = i)}{P(X)} = q_i(X)$$

But how do we determine p(X|y)?

COMPUTING P(X | Y)

Recall...

y - the class label

X – input attributes (features)

 Consider a dataset with 16 attributes (lets assume they are all binary). How many parameters to we need to estimate to fully determine p(X|y)?

Learning the values for the full conditional probability table would require enormous amounts of data

NAÏVE BAYES CLASSIFIER

• Naïve Bayes classifiers assume that given the class label (Y) the attributes are **conditionally independent** of each other:

$$X = \begin{bmatrix} x^1 \\ \vdots \\ x^n \end{bmatrix}$$

$$p(X|y) = \prod_{j} p_{j}(x^{j}|y)$$

Product of probability terms

Specific model for attribute *j*

Using this idea the full classification rule becomes:

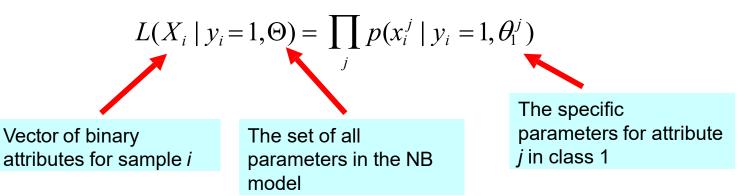

$$\hat{y} = \operatorname{arg\,max}_{v} p(y = v \mid X)$$

$$= \operatorname{arg\,max}_{v} \frac{p(X \mid y = v) p(y = v)}{p(X)}$$

$$= \operatorname{arg\,max}_{v} \prod_{j} p_{j}(x^{j} \mid y = v) p(y = v)$$

v are the classes we have

CONDITIONAL LIKELIHOOD: FULL VERSION

Note the following:

- 1. We assume conditional independence between attributes given the class label
- 2. We learn a **different** set of parameters for the two classes (class 1 and class 2).

LEARNING PARAMETERS

$$L(X_i | y_i = 1, \Theta) = \prod_j p(x_i^j | y_i = 1, \theta_1^j)$$

- Let $X_1 ... X_{k1}$ be the set of input samples with label 'y=1'
- Assume all attributes are binary
- To determine the MLE parameters for $p(x^j = 1 | y = 1)$ we simply count how many times the j'th entry of those samples in class 1 is 0 (termed n0) and how many times its 1 (n1). Then we set:

$$p(x^{j}=1|y=1) = \frac{n1}{n0+n1}$$

FINAL CLASSIFICATION

 Once we computed all parameters for attributes in both classes we can easily decide on the label of a new sample X.

Can be easily be

$$\hat{y} = \arg\max_{v} p(y = v \mid X)$$

$$= \arg\max_{v} \frac{p(X \mid y = v) p(y = v)}{p(X)}$$

$$= \arg\max_{v} \prod_{j} p_{j}(x^{j} \mid y = v) p(y = v)$$

Perform this computation for both class 1 and class 2 and select the class that leads to a higher probability as your decision

Prior on the prevalence of samples from each class

extended to multi-class

EXAMPLE: TEXT CLASSIFICATION

What is the major topic of this article?

If the Presidential election continues on its current course, historians may well look back on the third weekend in September as the moment when Donald Trump came closest to the White House, while millions of Americans reached for the Xanax. That Saturday, Hillary Clinton's lead over Trump narrowed to one percentage point in the widely watched Real Clear Politics poll average, which combines the results from a number of surveys. A day later, Clinton's lead fell to 0.9 percentage points.

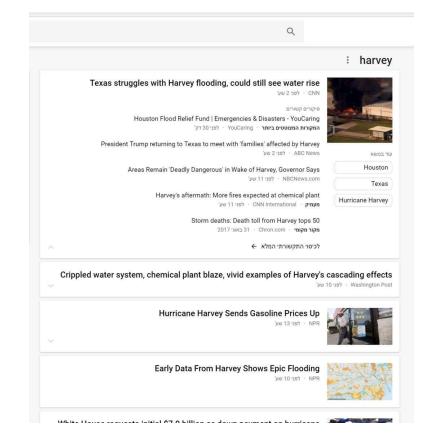

As the candidates head into the second Presidential debate, Clinton has had three good weeks in a row, during which Trump has been falling further behind.

Photograph by Eric Thayer / The New York Times / Redux

EXAMPLE: TEXT CLASSIFICATION

 Text classification is all around us

FEATURE TRANSFORMATION

- How do we encode the set of features (words) in the document?
- What type of information do we wish to represent? What can we ignore?
- Most common encoding: 'Bag of Words'
- Treat document as a collection of words and encode each document as a vector based on some dictionary
- The vector can either be binary (present / absent information for each word) or discrete (number of appearances)
- Google is a good example
- Other applications include job search adds, spam filtering and many more.

FEATURE TRANSFORMATION: BAG OF WORDS

- In this example we will use a binary vector
- For document X_i we will use a vector of m* indicator features {φ(X_i)} for whether a word appears in the document
 - $\phi(X_i)$ = 1, if word j appears in document X_i ; $\phi(X_i)$ = 0 if it does not appear in the document
- $\Phi(X_i) = [\phi^1(X_i) \dots \phi^m(X_i)]^T$ is the resulting feature vector for the entire dictionary for document X_i
- For notational simplicity we will replace each document X_i with a fixed length vector $\Phi_i = [\phi^1 \dots \phi^m]^T$, where $\phi = \phi(X_i)$.

EXAMPLE

Dictionary

- Washington
- Congress

. . .

- 54. Trump
- 55. Clinton
- 56. Russia

$$\phi^{54} = \phi^{54}(X_i) = 1$$

 $\phi^{55} = \phi^{55}(X_i) = 1$
 $\phi^{56} = \phi^{56}(X_i) = 0$

Assume we would like to classify documents as election related or not.

TRUMP IN DEEP TROUBLE ON EVE OF SECOND DEBATE

I f the Presidential election continues on its current course, historians may well look back on the third weekend in September as the moment when Donald Trump came closest to the White House, while millions of Americans reached for the Xanax. That Saturday, Hillary Clinton's lead over Trump narrowed to one percentage point in the widely watched Real Clear Politics poll

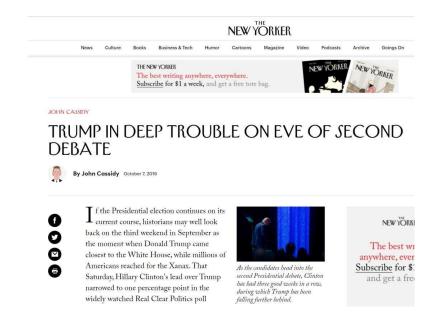

As the candidates head into the second Presidential debate, Clinton has had three good weeks in a row, during which Trump has been falling further behind. The best we anywhere, ever Subscribe for \$:

EXAMPLE: CONT.

We would like to classify documents as election related or not.

- Given a collection of documents with their labels (usually termed 'training data') we learn the parameters for our model.
- For example, if we see the word 'Trump' in n1 out of the n documents labeled as 'election' we set p('Trump'|'election')=n1/n
- Similarly we compute the priors
 (p('election')) based on the
 proportion of the documents from
 both classes.

EXAMPLE: CLASSIFYING ELECTION (E) or Sports (S)

Assume we learned the following model

$$\begin{array}{lll} P(\phi^{trump}=1 \mid E) = 0.8, & P(\phi^{trumo}=1 \mid S) = 0.1 & P(S) = 0.5 \\ P(\phi^{trump}=1 \mid E) = 0.9, & P(\phi^{trumo}=1 \mid S) = 0.05 & P(E) = 0.5 \\ P(\phi^{trump}=1 \mid E) = 0.9, & P(\phi^{trumo}=1 \mid S) = 0.05 & P(E) = 0.5 \\ P(\phi^{trump}=1 \mid E) = 0.9, & P(\phi^{trumo}=1 \mid S) = 0.05 & P(\phi^{trumo}=1 \mid E) = 0.1, & P(\phi^{trumo}=1 \mid S) = 0.7 & P(\phi^{trumo}=1 \mid S)$$

Assume we have the following feature vector for a document:

$$\phi^{\text{trump}} = 1$$
, $\phi^{\text{russia}} = 1$, $\phi^{\text{clinton}} = 1$, $\phi^{\text{football}} = 0$

$$P(y = E \mid 1,1,1,0) \propto 0.8*0.9*0.9*0.9*0.5 = 0.5832$$

 $P(y = S \mid 1,1,1,0) \propto 0.1*0.05*0.05*0.3*0.5 = 0.000075$

So the document is classified as 'Election'

NAÏVE BAYES CLASSIFIERS FOR CONTINUOUS VALUES

So far we assumed a binomial or discrete distribution for the data given the model $(p(X_i|y))$

However, in many cases the data contains continuous features:

- Height, weight
- Levels of genes in cells
- Brain activity

For these types of data we often use a Gaussian model In this model we assume that the observed input vector X is generated from the following distribution

$$X \sim N(\mu, \Sigma)$$

POSSIBLE PROBLEMS WITH NAÏVE BAYES CLASSIFIERS: ASSUMPTIONS

- In most cases, the assumption of conditional independence given the class label is violated
 - much more likely to find the word 'Donald' if we saw the word 'Trump' regardless of the class
- This is, unfortunately, a major shortcoming which makes these classifiers inferior in many real world applications
- There are models that can improve upon this assumption without using the full conditional model.

USING THE PRODUCT RULE

- Applies to any number of variables:
 - P(a, b, c) = P(a, b|c) P(c) = P(a|b, c) P(b, c)
 - P(a, b, c | d, e) = P(a | b, c, d, e) P(b, c | d, e)
- Factoring: (AKA Chain Rule for probabilities)
 - By the product rule, we can always write:

$$P(a, b, c, ... z) = P(a | b, c, ... z) P(b, c, ... z)$$

We often use comma to abbreviate AND.

Repeatedly applying this idea, we can write:

$$P(a, b, c, ... z) = P(a | b, c, z) P(b | c, ... z) P(c | ... z) ... P(z)$$

This holds for any ordering of the variables
